ENGIFLOW AI | ELECTRICAL SPECIFICATION

Revision B — intentionally conflicting test fixture

FICTIONAL TRAINING DOCUMENT — NOT FOR DESIGN, PROCUREMENT, OR CONSTRUCTION

Project: Example Data Center Power Infrastructure | **Revision:** B | **Date:** October 2026

1. Purpose and comparison instructions

This PDF is a fictional second document created to test EngiFlow AI cross-document conflict scanning. Upload it to the **same project** as the earlier Revision A sample PDF. Differences are intentional and do not represent approved engineering changes.

2. Design power capacity

The nominal electrical design capacity is 3 MW. This proposed Revision B value intentionally differs from the Revision A nominal electrical design capacity of 2 MW. These values must not be treated as approved design ratings.

3. Peak IT load

The peak IT demand is 2.2 MW. This is an illustrative Revision B planning scenario; no load study has been validated.

4. DC distribution voltage

The DC bus voltage is 1000 VDC. This differs from the previously documented 800 VDC bus and requires engineering review of equipment compatibility, insulation, protection, and conversion design.

5. Battery energy storage

The usable energy capacity is 750 kWh. This proposed Revision B battery value is for extraction and comparison tests only.

6. AC frequency

The AC frequency is 60 Hz. This is intentionally unchanged from the earlier sample and should **not** be flagged as a conflict when both documents are parsed.

7. Main transformer rating

The main transformer rating is 3000 kVA. This is a different example rating from the earlier sample's 2,500 kVA; note the earlier wording may not match the current scanner's strict pattern.

8. Open review questions

Confirm whether Revision B replaces Revision A or represents a different operating scenario. Establish the controlling design revision, validate loading assumptions, document required electrical studies, and obtain qualified engineering review before using any values.

Important: This document is deliberately fabricated. EngiFlow AI findings are text-comparison test results, not evidence of a real engineering defect.
